For

LOW PROFILE HIGH-STRENGTH VEHICLE DOORBEAM

Docket No.

07198.85607-001

Mail Stop Amendment Commissioner for Patents P. O. Box 1450 Alexandria, VA 22313-1450

DECLARATION OF SAI GADAMUNDER 37 CFR 1.132

- 1. I, Sai Gadam, am an employee of Shape Corp. (SHAPE) of Grand Haven, Michigan, the Assignee of the above identified application.
- 2. I have been an employee of SHAPE for two (2) years, and am currently employed as Computer Aided Engineering (CAE) Manager. As such, I am familiar with vehicle doorbeams.
- 3. As an employee of SHAPE, I work daily with the testing and modeling of components, such as the strength testing of vehicle doorbeams. This testing includes testing with the aid of finite element analysis software.
- I am familiar with the low profile high-strength vehicle doorbeam 4. constructions that are disclosed in the present application, including the construction shown in Fig. 2 having a first weld line at the lateral edges 26,28 of the beam and a second weld line at line 32 of the beam (SHAPE DOUBLE-WELD DOORBEAM), and also including the construction shown in Fig. 2 having only the first weld line (SHAPE SINGLE-WELD DOORBEAM).

- 5. I have reviewed U.S. Patents 6,591,577 to Goto (GOTO) and 5,934,544 to Lee (LEE), and I understand the construction of the doorbeam disclosed in GOTO (GOTO DOORBEAM) and the beam disclosed in LEE (LEE BEAM).
- 6. Using techniques that are well known to those in the art, I used finite element analysis to model and compare the respective strengths and load-bearing capabilities of the SHAPE DOUBLE-WELD DOORBEAM, the SHAPE SINGLE-WELD DOORBEAM, the GOTO DOORBEAM, and the LEE BEAM.
- 7. The finite element analysis was performed using LS-DYNA software, a well known finite element analysis software.
- 8. The geometries of the SHAPE DOUBLE-WELD DOORBEAM, the SHAPE SINGLE-WELD DOORBEAM, the GOTO DOORBEAM, and the LEE BEAM were modeled using conventional computer aided design software. Illustrations of the SHAPE DOUBLE-WELD DOORBEAM model and the SHAPE SINGLE-WELD DOORBEAM model are shown in the attached Appendix A, titled "SHAPE DOOR BEAM." An illustration of the GOTO DOORBEAM is shown in Appendix B, titled "GOTO DOOR BEAM." An illustration of the LEE BEAM is shown in Appendix C, titled "LEE DOOR BEAM." The geometry data was compiled from the above identified patent application; the GOTO patent; and the LEE patent. Models of each geometry were created based on the finite element sizes that were believed to produce the most accurate results. For instance, in some cases portions of the beams are modeled and shown as discrete elements instead of smooth, rounded surfaces because the use of smaller elements would produce inaccurate results.

: -3-

9. The models were then entered into the finite element analysis software, along with material data for each doorbeam 10. The Shape doorbeam has different material properties in the central portion of the beam, the transitional portions of the beam, and the attachment portions, because the Shape doorbeam is formed by roll-forming the web and then heat treating the ends to form the attachment portions. In order to focus the analysis on the respective constructions of each respective beam, the LEE BEAM and the GOTO DOORBEAM were modeled with the same material properties. Therefore, the modeled material data was the same for the SHAPE DOUBLE-WELD DOORBEAM, the SHAPE SINGLE-WELD DOORBEAM, the GOTO DOORBEAM, and the BEAM. The material data is as follows:

Central Beam Portion (illustrated in red): Martensite M220 Steel (Tensile Strength: 220,000 psi)

Transitional portions (illustrated in blue): Martensite M120 Steel (Tensile Strength: 120,000 psi)

Attachment Portions (illustrated in yellow): Martensite M80 Steel (Tensile Strength: 80,000 psi)

The doorbeams were each modeled with the same material thickness (1.76mm). The cross-sectional illustrations shown in the Appendices do not show actual material thicknesses. The lines in the illustrations show the center line of the materials. This is the reason for certain apparent "gaps" in the illustrations (e.g. between the flanges and the base portion of the LEE doorbeam). These gaps do not exist in the actual models.

10. After the data was entered, I ran the finite element analysis software in order to provide a model of the load that each doorbeam could absorb when deflected. The finite

: Melvin J. Guiles

Page No.

: -4-

element analysis was intended to approximate the performance of the SHAPE DOUBLE-WELD DOORBEAM, the SHAPE SINGLE-WELD DOORBEAM, the GOTO DOORBEAM, and the LEE BEAM under real-life forces, such as those experienced in an automobile accident. Specifically, the finite element analysis was used to approximate the amount of load required to deflect the center of each doorbeam. The analysis calculated the load absorbed by the center of each doorbeam when the ends of the respective doorbeams were attached to springs, and the center of the doorbeam was deflected in increasing amounts. The loads were applied perpendicularly to the center of each doorbeam to simulate a vehicle side impact.

- 11. The results of the finite element analysis clearly indicate that both the SHAPE DOUBLE-WELD DOORBEAM and the SHAPE SINGLE-WELD DOORBEAM are capable of absorbing higher loads than the GOTO DOORBEAM and the LEE BEAM. In other words, greater loads are required to deflect the Shape doorbeams than the Lee or Goto doorbeams. This is evidenced by the plot (Appendix D) of Load (kN) versus Displacement (mm) for all of the doorbeams. The modeled SHAPE DOUBLE-WELD DOORBEAM, shown in green, and the modeled SHAPE SINGLE-WELD DOORBEAM, shown in pink, both absorbed approximately a 17 kN load when deflected 170 mm. The modeled GOTO DOORBEAM, shown in dotted green, absorbed approximately a 13.2 kN load, and the modeled LEE BEAM, shown in dotted yellow, absorbed approximately a 15.1 kN load when deflected the same amounts.
- 12. When the doorbeams have the same thickness as described in the preceding paragraphs, the respective weights of the doorbeams vary. Specifically, when each

: Melvin J. Guiles

Page No.

: -5-

beam has a thickness of 1.76 mm, the weight of both the SHAPE DOUBLE-WELD and SHAPE SINGLE-WELD doorbeams is 3.252 kgs, the weight of the GOTO DOORBEAM is 3.515 kgs, and the weight of the LEE BEAM is 4.109 kgs.

- doorbeams. Therefore, a heavier doorbeam is less competitive than a lighter doorbeam having the desired performance characteristics. I therefore also modeled the GOTO DOORBEAM and the Lee BEAM at material thicknesses that would result in beams having the same weight as the modeled SHAPE DOORBEAMS. Such reduced material thickness likely would be required for truly competitive products. The thickness of the alternative GOTO DOORBEAM at 3.252 kgs is 1.6 mm and the thickness of the alternative at 3.252 kg LEE BEAM is 1.4 mm. The alternate GOTO DOORBEAM, shown in solid blue in Appendix D, absorbed approximately a 12.9 kN load when deflected 170 mm, the alternate LEE BEAM, shown in orange in Appendix D, absorbed approximately a 13 kN load when deflected 170 mm.
- 14. The plot of Appendix D further shows a second alternative for the LEE BEAM, wherein weld lines are hypothetically added between the flanges and the base of the doorbeam as illustrated in the lower right corner of Appendix L. This second alternate LEE BEAM, shown in dotted blue, absorbed approximately a 15.1 kN load when deflected 170 mm.
- 15. The designs modeled as described in the preceding two paragraphs show that 1) at the same material thickness, the Shape beams provide superior performance, 2) that at the same beam weight, the Shape beams provide superior performance and 3) even with hypothetical weld lines added to Lee, the Shape doorbeam provides superior performance.

16. The plots shown in Appendix D each have a wave-like pattern. This is due to the sampling rate of the finite element analysis. Greater sampling rates can be used in order to reduce the wave-like pattern, however, this would not have a significant effect on the maximum loads seen in the plots.

17. I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

LOW PROFILE HIGH-STRENGTH VEHICLE DOORBEAM

Docket No.

07198.85607-001

Mail Stop Amendment Commissioner for Patents P. O. Box 1450 Alexandria, VA 22313-1450

DECLARATION OF MELVIN J. GUILES UNDER 37 CFR 1.132

- 1. I, Melvin J. Guiles, am the sole inventor named in the above identified application. I am also an employee of Shape Corp. (SHAPE) of Grand Haven, Michigan, the Assignee of the above identified application.
- 2. I have been an employee of SHAPE for five (5) years, and am currently employed as Director of Technology and Advanced Engineering. As such, I am familiar with vehicle doorbeams.
- 3. As an employee of SHAPE, I work daily with the design and manufacture of components, such as roll-formed vehicle doorbeams.
- I am familiar with the low profile high-strength vehicle doorbeam 4. constructions that are disclosed in the present application, including the construction shown in Fig. 2 having a first weld line at the lateral edges 26,28 of the beam and a second weld line at line 32 of the beam (SHAPE DOUBLE-WELD DOORBEAM), and also including the construction shown in Fig. 2 having only the first weld line (SHAPE SINGLE-WELD DOORBEAM).

: -2-

5. I have reviewed U.S. Patents 6,591,577 to Goto (GOTO) and 5,934,544 to Lee (LEE), and I understand the construction of the doorbeam disclosed in GOTO (GOTO DOORBEAM) and the beam disclosed in LEE (LEE BEAM).

- 6. In view of my experience and knowledge of the design and manufacture of doorbeams, my analysis of the above noted beam constructions is that the SHAPE SINGLE-WELD DOORBEAM and the SHAPE DOUBLE-WELD DOORBEAMS are capable of being formed from higher tensile strength materials than the GOTO DOORBEAM or the LEE BEAM. When material thickness is held constant, it is more difficult to roll form materials of higher tensile strength than materials of lower tensile strength. The GOTO DOORBEAM and the LEE BEAM both require bending the material into tight radii that are not required by the Shape doorbeams. For example, both the GOTO DOORBEAM and the LEE BEAM require lateral portions that are bent at approximately 90 degree angles into flanges that abut the beam. Because the Shape construction does not require these tight radii, the Shape doorbeam is capable of being formed from materials of higher tensile strength than the beams disclosed by Goto and Lee.
- 7. I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.
